# All-to-All Optical Switch

- Popular example: arrayed waveguide grating routers (AWGRs). All-to-all connectivity. Equal number of wavelengths from every source to every destination
- State of the art example: 400 x 400, 400 wavelengths per port, 25 GHz bandwidth per wavelength
- Y. Hida et al., “400-channel 25-ghz spacing arrayed-waveguide grating covering a full range of c- and l-bands,” in OFC 2001
- Challenge: Single wavelength’s bandwidth may not be adequate. Requires indirect routing

# Spatial Optical Switch

- Popular examples: microelectromechanical systems (MEMS), microring resonators (MRRs)
- All wavelengths are connected from one port to another port
- State of the art example (MEMS): 240x240, one wavelength per port
- Challenge: Quantization of bandwidth. For example, 21 wavelengths escape an MCM

# Other Considerations

- “Intermediate” optical switches exist: Wave-selective
- Wave-selective and spatial switches reconfigure in micro to milli seconds
- CXL can be the link protocol
- Forward error correction can achieve necessary bit error rates with only an additional 5ns latency
- With modern photonic links, **we meet all design goals**. But what about the additional latency?

# Speedup Over Electronic Switches

# [Call to Action]

- Lets build efforts on the usability and programmability of resource-disaggregated systems: resource allocation algorithms, usage monitoring, programming models, runtime management, etc.
- Contact the speaker: [mihelog@lbl.gov](mailto:mihelog@lbl.gov)
- More information on the project ecosystem:
